1 Introduction and Background

This document will help install and setup a docker instance of FEniCSx used for 2.077. We will be using FEniCSx 0.8.0 Dev.

While this is an unstable version right now it is the only version with good Quadrature Element support. If you want the stable version just pull the image:

```
1 > docker pull jorgenin/dolfinx-2.077:v0.7
```

Listing 1: Docker Pull Command

These instructions are made specifically with Mac OS in mind, but after installing docker, the process should be platform independent.

2 Docker

WARNING: Please backup your data. Data stored in a container may be lost at any time. Use git or a volume to ensure your data is well protected.

2.1 What is Docker

Docker is a platform that uses containerization technology to simplify the deployment and management of software applications. In the context of software development, especially for complex engineering applications like FeniCSx, Docker offers several advantages:

- Containerization:
 - Containers are isolated environments where applications can run. They are lightweight because they share the host system's kernel (but not the OS itself) and are not burdened with the overhead of a virtual machine.
 - For FEniCSx, this means that each instance of the application runs in a consistent environment, irrespective of the underlying hardware or software configurations of the host system.
- Consistency and Reproducibility:
 - Docker ensures that FEniCSX runs identically on every machine, avoiding the common "it works on my machine" problem in software development.
- Ease of Distribution and Version Control:
 - Docker images (blueprints for containers) can be version-controlled and shared through Docker Hub or other registries, ensuring that all students and researchers access the same version of FEniCSX and its dependencies.

Because of these advantages, we will be using Docker to run FEniCSx.

2.2 Installing Docker

It is recommended that you install docker desktop for first time use. You can find the download here: [Docker Desktop](#) and download the appropriate version for your operating system. An account is not necessary for basic install and usage.

After downloading open up the image and drag it into the applications folder. Docker should now be installed.

Figure 1: Docker install process

After docker has finished installing open up the docker desktop application. The application may not instantly open. Instead it may be in the background, look at figure 2 to see if you're docker is in the background.

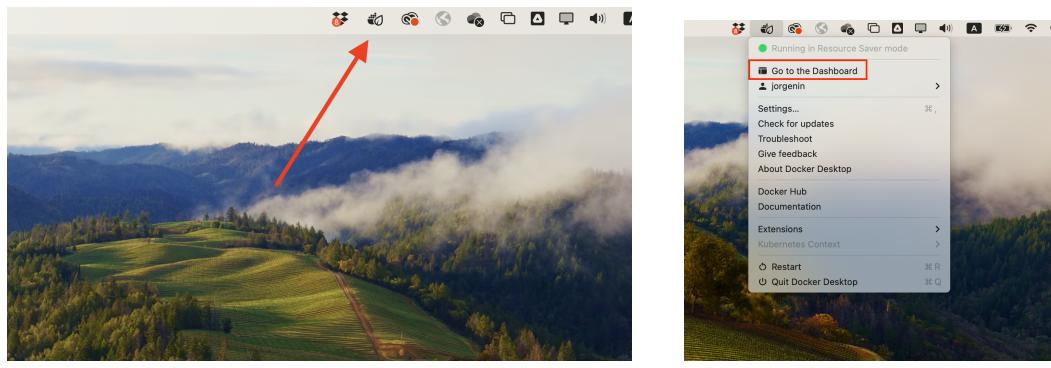

Figure 2: How to check if docker is open in the background. Click on the "Go to dashboard" to open up docker.

2.3 Docker Layout

Once docker is open you should see a window similar to this. This is the dashboard.

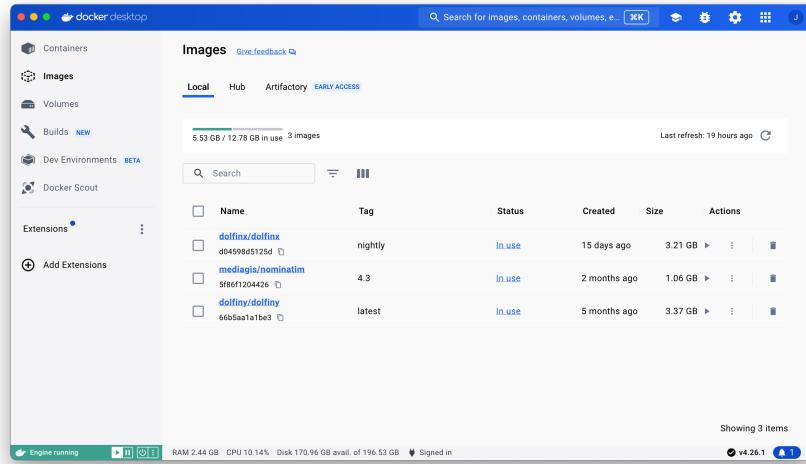

Figure 3: The Docker Dashboard

There are multiple tabs but we will only be covering two of them. The Containers tab, and the Images tab.

2.3.1 Images

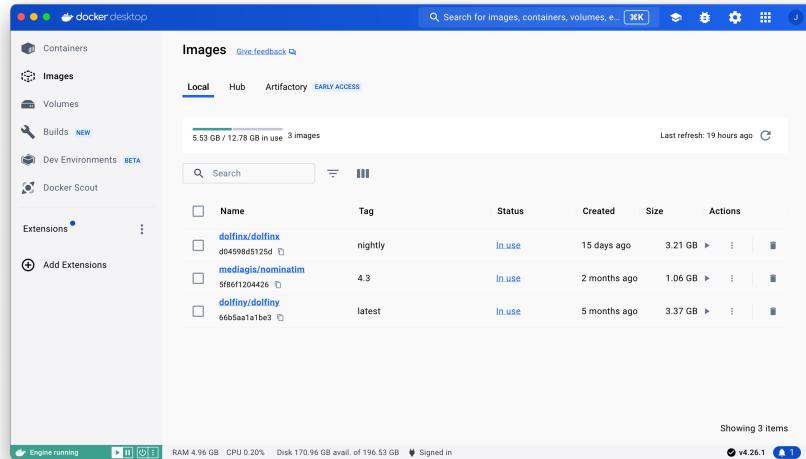

Figure 4: The Docker Images Tab

The docker images tab contains all of the Images you currently have installed. Images are essentially different operating systems you can have. If you want to run multiple version of FEniCSx for example you could have multiple images of it.

2.3.2 Containers

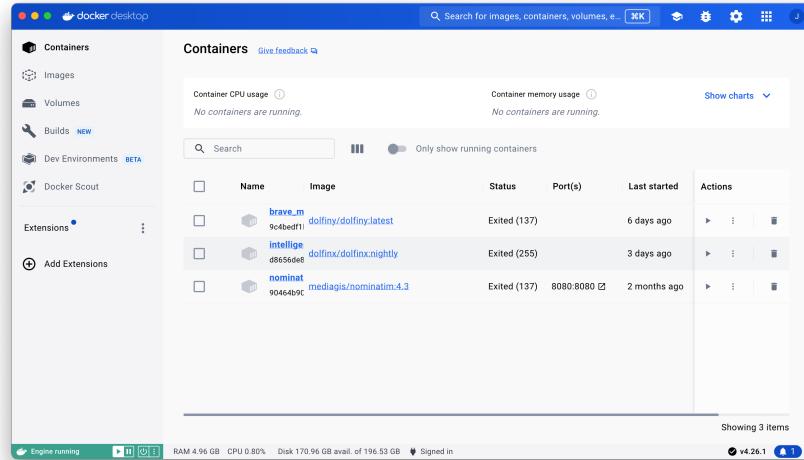

Figure 5: The Docker Containers Tab

The docker containers tab has all of the container you have setup. Each container is essentially a different instance of a specific image. It is normally recommended that for every project you have a different separate container made. Though those containers could use all the same image.

2.4 Recommended Settings

Because we will be running FEA software which will want to use most of our computers resources, there are a few changes that should be made to optimize performance.

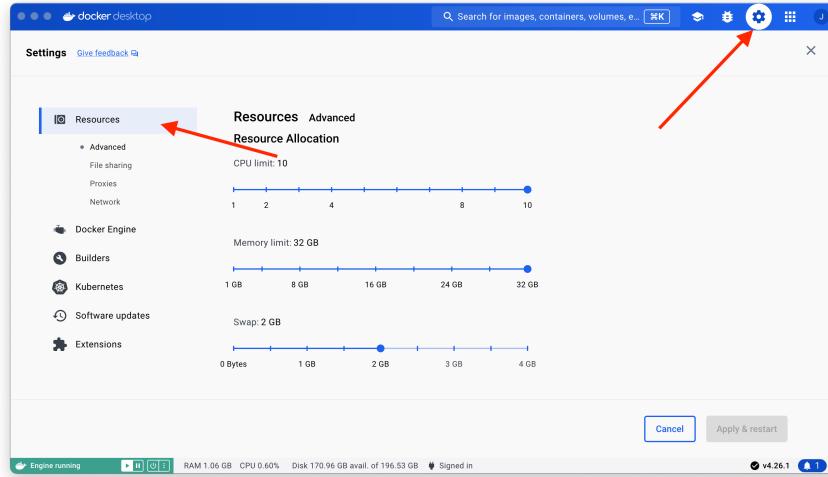

Figure 6: The Docker Settings tab

We will be going to the docker settings tab, and then resources as seen in Figure 6. In here we will be maximizing the number of CPU's available and the memory limit.

3 FEniCSx Container Setup

In this section we will be setting up the FEniCSx image and container so that it runs properly. We will also explain how to mount a folder in the volume so that it is shared between the host and docker container.

3.1 Pulling the Image

First we will need to pull the image from the docker hub. To do this we will need to open up the terminal.

On a mac we can press ctrl+space and then type in terminal to open it up.

Figure 7: The Docker Settings tab

Once the terminal is open we will need to type in the following command:

```
1 > docker pull jorgenin/dolfinx-2.077:v0.8
```

Listing 2: Docker Pull Command

Which will download the image and prepare it on your computer.

Figure 8 shows what the output will be.

```

[jorgenin@Jorges-MacBook-Pro ~ % docker pull jorgenin/dolfinx-2.077
Using default tag: latest
latest: Pulling from jorgenin/dolfinx-2.077

jorgenin@Jorges-MacBook-Pro ~ %

```

Figure 8: Output from the terminal

3.2 Creating the Container

Now that we have the image downloaded we can create a container from it.

```
1 > docker run -it jorgenin/dolfinx-2.077:v0.8
```

Listing 3: Docker Pull Command

This command will create the container and run it in interactive mode. Explaining it in more detail:

`docker run` will create a container from the image we specify. `-it` will run the container in interactive mode. `jorgenin/dolfinx-2.077` is the image we want to use. `:v0.8` is the tag. We could also use for example `:latest` to get the latest version of the image or `:v0.7` to get the 0.7 version of the image.

Upon executing this command we will be inside of the container and activly running the image.

If we look at the docker desktop application we will see that a container has been created as showing in Figure 9

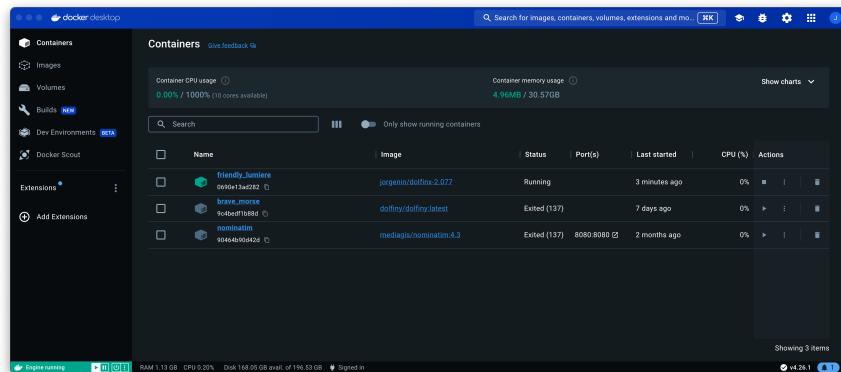

Figure 9: And image from the docker desktop application showing the docker container running.

We can exit the container by typing `exit`.

3.3 Connecting to a Container that was created

If we run the past section multiple times we'll create multiple independent containers. As such when developing we'll normally want to just connect to a container that has already been created.

We can do that through either the terminal or the docker desktop application.

3.3.1 Connecting through a terminal

We can run the following command to run the container interactively (connecting to the container immediately)

```
1 > docker start -i "container name": "container tag"
```

If we look at Figure 9 we can see the container we created is called `friendly_lumiere`. So in our case the command would be:

```
1 > docker start -i friendly_lumiere
```

If we just want the command to run the background we can just omit the `-i`. This has the advantage that if we close the terminal the container will continue to run.

```
1 > docker start friendly_lumiere
```

We could then connect to it at any point by running:

```
1 > docker attach friendly_lumiere
```

3.3.2 Connecting through the Docker Desktop Application

The docker desktop application is more intuitive (though it does have limitations). To start a container we can just click the play button next to the container we want to run as shown in Figure 10.

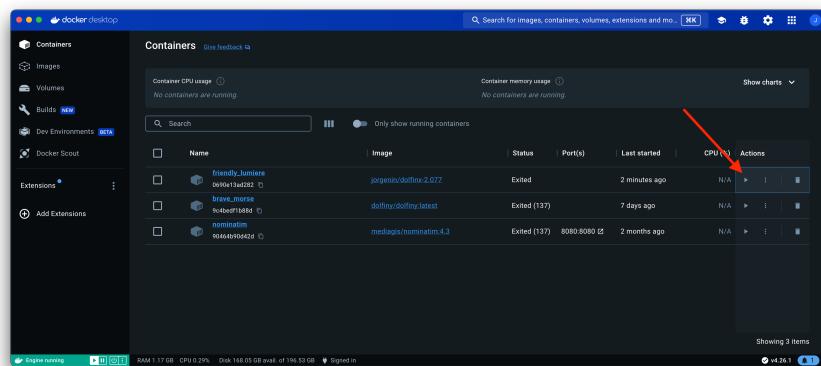

Figure 10: How to start a container in docker desktop

If we want to attach to a running container we can then click on the three dots and then click on `Open In Terminal` as seen in 11

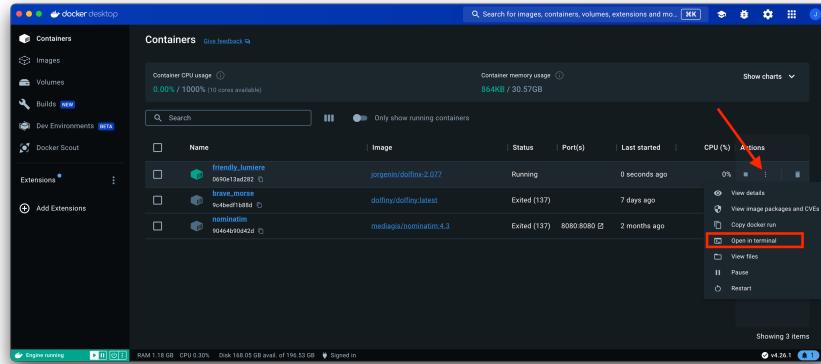

Figure 11: How to Connect to DockerTerminal

3.4 Sharing A Folder

To share (or mount) a folder between the host and the container we will need to use the `-v` flag when creating the container.

```
> docker run -it -v "folder path":container folder path jorgenin/dolfinx-2.077:v0.8
```

For example if we wanted to share the folder `/users/jorgenin/Documents/2.077-FEniCSx-Finite-Elasticity` with the container we would run the following command:

```
> docker run -it -v /users/jorgenin/Documents/2.077-FEniCSx-Finite-Elasticity:/home/project jorgenin/dolfinx-2.077:v0.8
```

Now any files that are in the folder on the OS will be shown to the container and viceversa.

4 VSCode

VS Code will be our main development software we will be using. It's very flexible and supports a multitude of programming languages. To install it download it from Microsoft here [VSCode Download](#) and install it. The process is very similar to installing docker.

4.1 VSCode Extensions

The main idea behind vscode is that can be easily customized to any usecase through the liberal use of extensions.

To simplify the process we have created a custom extension pack with most everything you'll need to get started. To download and install it click on the following link: [VSCode FEniCSx Extension Pack](#) and click on install.

Another way to do so (and to install your own extensions) is to click on the extensions tab on the left side of the screen and then search for the extension you want to install. You can see the process in Figure 12.

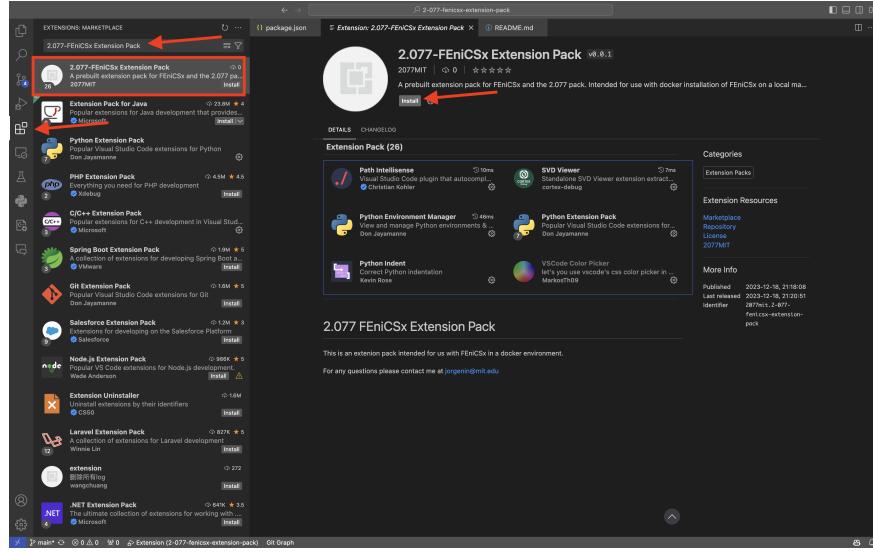

Figure 12: How to install extensions in vscode

5 Running Example Program

With the previous steps completed we should now be prepared to actually run a real example. Here I will walk through step by step from initializing an image to finally running it, and connecting to it through VS Code.

Through this section we will assume you have done all of the basic setup steps previous mentioned.

5.1 Pulling the Image

To pull an image we will open up a terminal and run the command:

```
1 > docker pull jorgenin/dolfinx-2.077:v0.8
```

Listing 4: Docker Pull Command

We will see the following output from the terminal:

```

jorgenin@Jorges-MacBook-Pro ~ % docker pull jorgenin/dolfinx-2.077
Using default tag: latest
latest: Pulling from jorgenin/dolfinx-2.077
c391327a0fid: Already exists

docker.io/jorgenin/dolfinx-2.077:latest
jorgenin@Jorges-MacBook-Pro ~ %

```

Figure 13: Output from the terminal

5.2 Creating the Container

Here we will be creating the container and mounting a local folder to it from where we will be running all of the results. We will be mounting a folder `/Users/jorgenin/Desktop/fenicsx-tutorial` to the opening folder of the docker instance `/home/project`.

The command is:

```
1 > docker run -it -v /Users/jorgenin/Desktop/fenicsx-tutorial:/home/project jorgenin/dolfinx
-2.077:v0.8
```

Listing 5: Docker Pull Command

We can see the results in Figure 14.

```

jorgenin@Jorges-MacBook-Pro ~ % docker run -it -v ~/Desktop/fenicsx-tutorial:/home/project jorgenin/dolfinx-2.077
root@2116069bb8b9:/home/project#

```

Figure 14: Output from the terminal after mounting image

5.3 Connecting to the Container through VSCode

We now launch vscode and connect to the container we just created. We can go to the docker extension, find the container we just launched right click on it and then click attach `Visual Studio Code`.

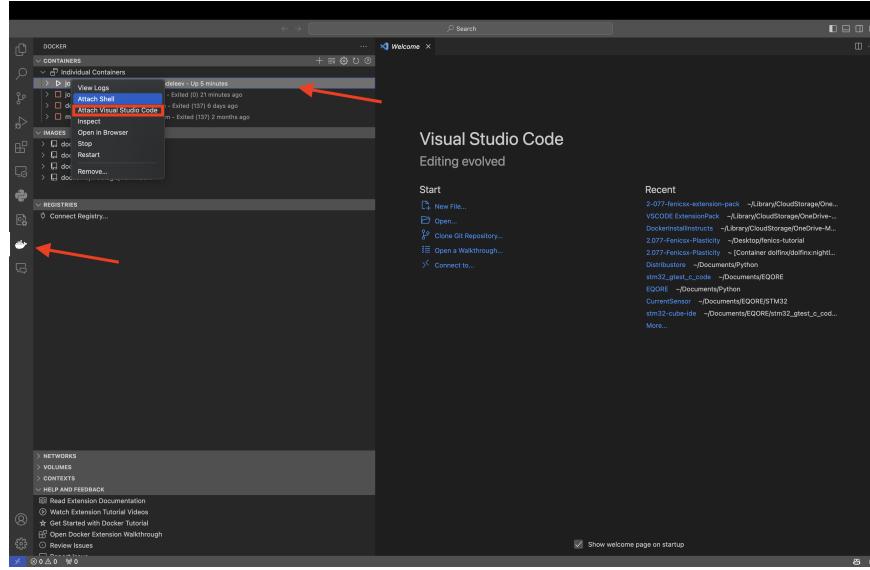

Figure 15: How to open up the docker extension and launch into the file. Right clicking on any of the containers will allow us to attach a VSCode instance.

This will open up a new tab of vscode. We can ensure we are connected by looking at the bottom left corner of the screen.

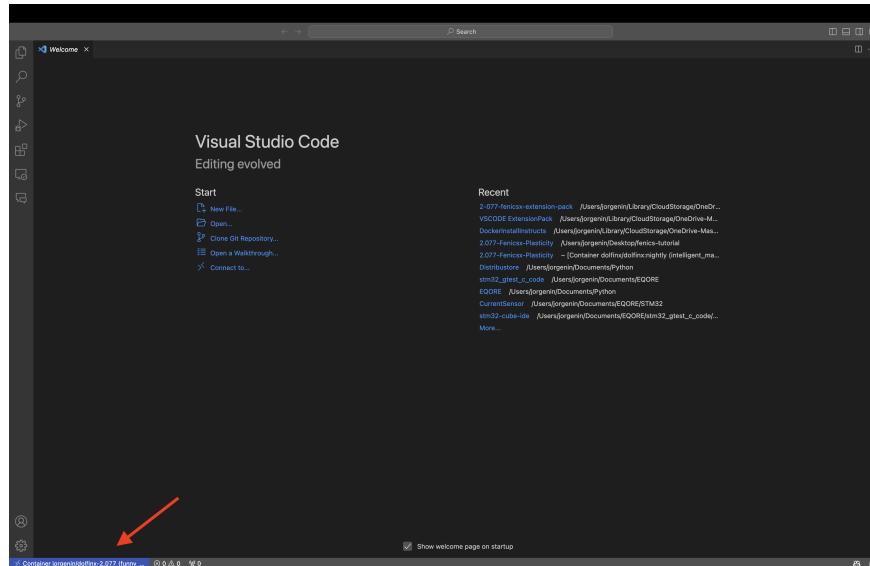

Figure 16: How to open up the docker extension and launch into the file. Right clicking on any of the containers will allow us to attach a VSCode instance.

5.4 Enabling Extensions In Container

By default VSCode extensions are not installed in the container. To enable them we can just go to the extensions, and search for the 2.077 FeniCSx exension pack and insall it.

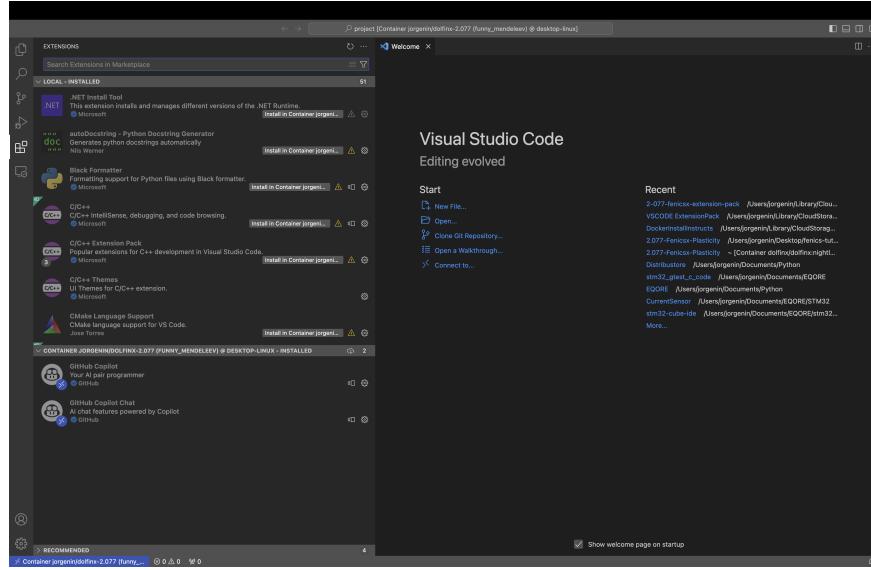

Figure 17: Extensions in the host are not automatically carried over to the container. It is the same process as before to install the extensions into the container.

5.5 Cloning a repository

We can now open up our code with VSCode.

By default VS-Code connects to the root folder of the container. We normally want to avoid adding files into here if possible. What we will do is use the terminal to clone a repository from git into the shared folder we created earlier. We will then open that folder with vscode.

We can open up the terminal by click on the terminal tab on the top of the screen and then clicking on new terminal.

The terminal will open in the bottom of the screen.

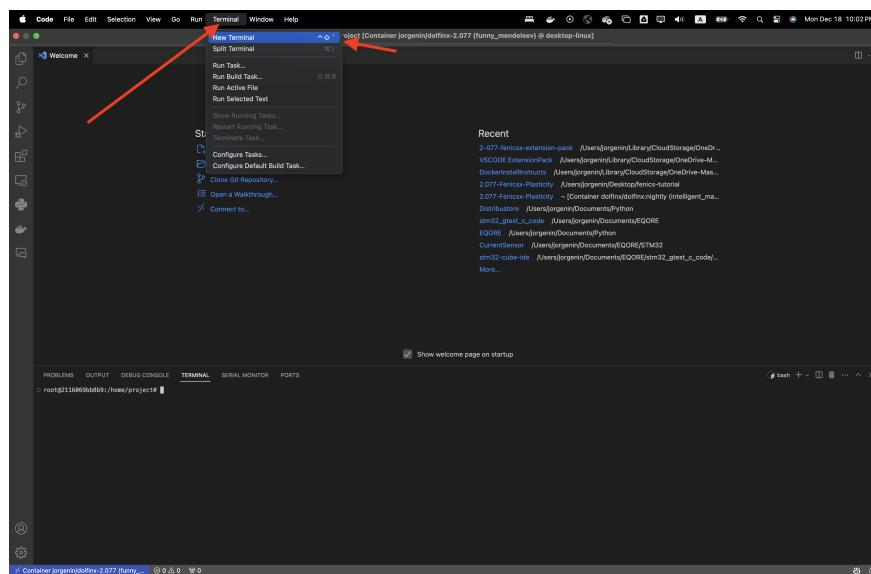

Figure 18: How to open a Terminal in VSCode

Our shared folder is `/home/project` so we will navigate to it by running the following command:

```
1 > cd /home/project
```

Listing 6: Docker Pull Command

We can then clone the repository by running the following command:

```
1 > git clone https://github.com/jorgenin/2.077-Fenicsx-Plasticity
```

Listing 7: Docker Pull Command

```
● root@2116069bb8b9:~# cd /home/project/
● root@2116069bb8b9:/home/project# git clone https://github.com/jorgenin/2.077-Fenicsx-Plasticity

2.077-Fenicsx-Plasticity
● root@2116069bb8b9:/home/project#
```

Figure 19: Ouput from the terminal after running commands

After Running the commands we can look in our host computer and see that the files were also in the shared folder. This is because we created the files in our shared folder.

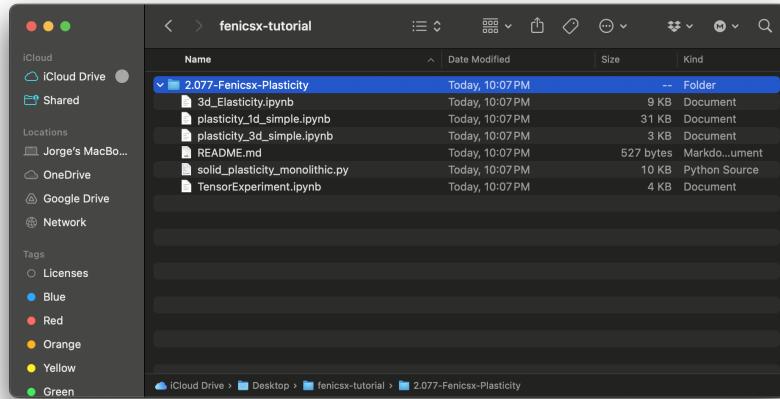

Figure 20: The git clone from the container also created the files in our shared folder. This is because we shared the folder initially when initializing the container.

5.6 Opening Folder and Running Example

We can now open up the folder in vscode and run the example.

We can do this in two ways, either in the welcome screen we can click open, or we can click on file and then on open. You can see this in figure 21.

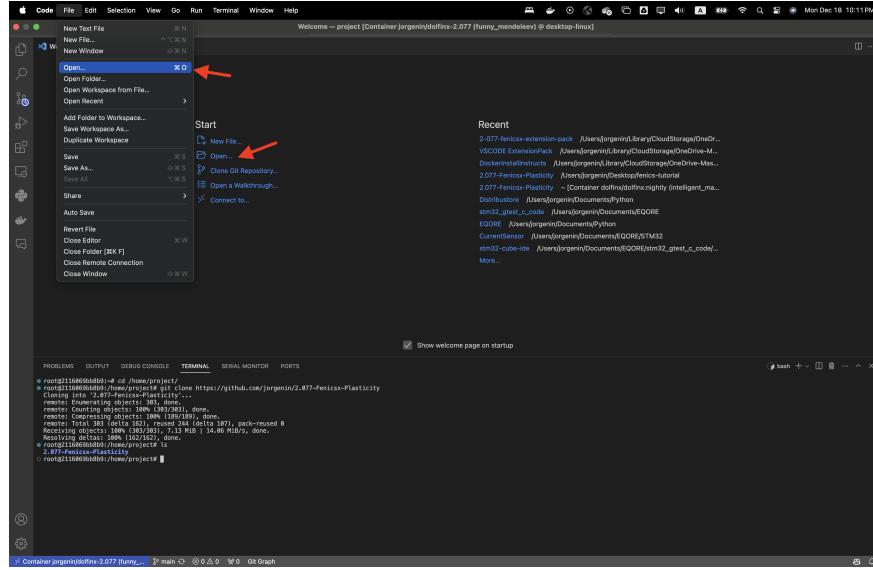

Figure 21: How to open a folder in VSCode

Either method opens the same window where we can select the folder we want to open. in this case we want to open the `2.077-Fenicsx-Plasticity` folder.

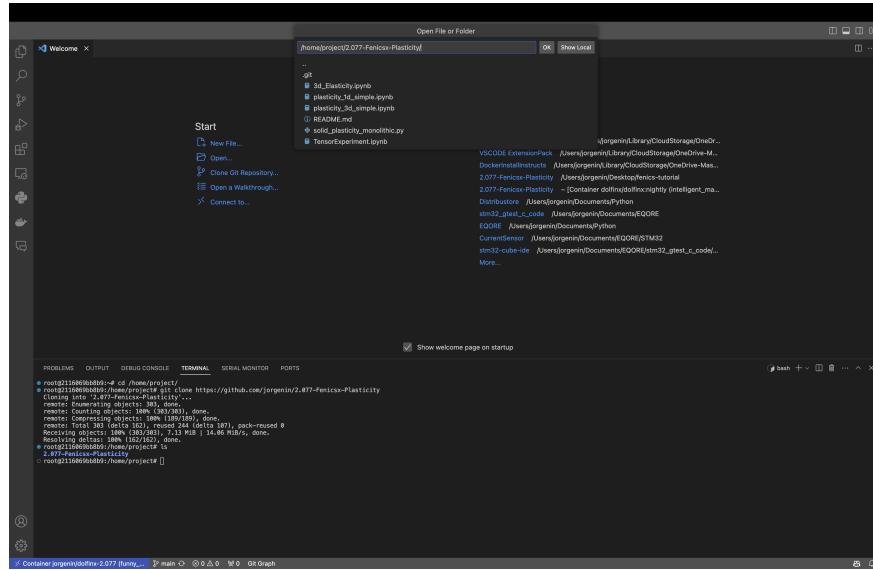

Figure 22: Selecting the FeniCSx Plasticity folder

We can now see the folder in the file explorer tab in VSCode. We can open up any file in the project and edit / or run it as necessary.

Jupyter notebooks will open inline. We can make sure we are using the right python verion (3.10 at the time of writing) and then clicking run all to run the entire example as seen in figure 23.

The screenshot shows a Jupyter Notebook interface within a Docker container. The notebook title is "3d_Plasticity_Bending.ipynb". The code cell contains Python code for a finite element analysis of a beam bending problem. Two red arrows point to the "Run All" button at the top of the code editor and the "Python 3.10.12" language selector dropdown.
